

Bayesian analysis of cross-sectional networks — Assignment in R

Maarten Marsman & Nikola Sekulovski

Learning goals

After completing this assignment, you will be able to

- 1) Test for edge presence or absence with the inclusion Bayes factor.
- 2) Estimate a cross-sectional network in a Bayesian framework with or without edge selection.
- 3) Visualize the results from the Bayesian analysis with a network plot and an edge evidence plot.
- 4) Interpret the results from a Bayesian analysis, such as the Bayes factor and credible interval.
- 5) Convey to others the advantages of using the Bayesian approach to network analysis.

Background Literature

For more background information, you can have a look at:

Huth, K. B. S., de Ron, J., Goudriaan, A. E., Luijckes, J., Mohammadi, R., van Holst, R. J., Wagenmakers, E.-J., & Marsman, M. (2023). Bayesian analysis of cross-sectional networks: A tutorial in R and JASP. *Advances in Methods and Practices in Psychological Science*, 6, 1-18.

Huth, K., Keetelaar, S., Sekulovski, N., van den Bergh, D., & Marsman, M. (2024). Simplifying Bayesian analysis of graphical models for the social sciences with easybgm: A user-friendly R-package. *Advances in psychology*, e66366.

Sekulovski, N., Keetelaar, S., Huth, K. B. S., Wagenmakers, E.-J., van Bork, R., van den Bergh, D., & Marsman, M. (in press). Testing Conditional Independence in Psychometric Networks: An Analysis of Three Bayesian Methods. *Multivariate Behavioral Research*.

Setup

Before starting the task in R, you need to install and load some packages. We have created the package `easybgm` to help you easily fit and visualize the results of your analyses.

```
# Install the required packages with install.packages("package") and
# load them using library("package")
library(readr)
library(BDgraph)
library(qgraph)
library(bgms)
library(easybgm)
```

The Data

Data background: This data is a subset from an online version of the Sexual Compulsivity Scale (Kalichman & Rompa, 1995) which is openly available at https://openpsychometrics.org/_rawdata/. The items were rated on a Likert scale (1=Not at all like me, 2=Slightly like me, 3=Mainly like me, 4=Very much like me):

- Q1. My sexual appetite has gotten in the way of my relationships.
- Q2. My sexual thoughts and behaviors are causing problems in my life.
- Q3. My desires to have sex have disrupted my daily life.
- Q4. I sometimes fail to meet my commitments and responsibilities because of my sexual behaviors.
- Q5. I sometimes get so horny I could lose control.
- Q6. I find myself thinking about sex while at work.
- Q7. I feel that sexual thoughts and feelings are stronger than I am.
- Q8. I have to struggle to control my sexual thoughts and behavior.
- Q9. I think about sex more than I would like to.
- Q10. It has been difficult for me to find sex partners who desire having sex as much as I want to.

Kalichman, S. C., & Rompa, D. (1995). Sexual Sensation Seeking and Sexual Compulsivity Scales: Validity, and Predicting HIV Risk Behavior. *Journal of Personality Assessment*, 65(3), 586–601.

```
data <- read_csv("data_scs.csv")
```

Part 1: Testing for conditional (in)dependence (*Is there an effect?*)

Task 1.1: Analyze the graphical model

See the help file of the `easybgm` package to familiarize yourself with the input arguments. Estimate a network model with `easybgm`. The data are ordinal, so be sure to specify this in the `type` argument.

Task 1.2: Extract the edge evidence plot and interpret the results.

(i) Compute the edge evidence plot with `plot_edgeevidence`. Take a look at the `split` argument, which may help with the interpretation. The `plot_edgeevidence` function also takes the same arguments as `qgraph`. Except for the `layout` argument which, due to a bug in the current CRAN version of `easybgm`, may need to be replaced with `layout_avg` if you want to customize the layout.

(i) What does the edge evidence plot show?

(ii) How do you interpret an edge inclusion Bayes factor? What is the default threshold value used in the `plot_edgееvidence` function?

Part 2: Estimation (*What is the effect?*)

Once we have tested for the presence of edges, the next step is to estimate the parameters for the present edges. We can do this in one of two ways. The first way is consistent with the way we tested for conditional independence and takes into account both structure and parameter uncertainty by using Bayesian variable selection methods. The second method estimates the parameters given only a single network structure — the fully connected structure. For more details on Bayesian model averaging, of which Bayesian variable selection is a special case, you can take a look at the following paper:

Hinne, M., Gronau, Q. F., van den Bergh, D., & Wagenmakers, E. J. (2020). A Conceptual Introduction to Bayesian Model Averaging. *Advances in Methods and Practices in Psychological Science*, 3(2), 200-215.

Task 2.1: Estimate the parameters with edge selection.

The object with the results from Part 1 already contains the averaged model parameters using edge selection, therefore you can use this object.

- (i) Visualize the network using `plot_network`, which will give you the median probability model.
- (ii) What conclusions can you draw from the estimated network?
- (ii) What does it mean that this network is based on the median probability model, how does this relate to the inclusion Bayes factors which you have calculated in Part 1?
- (ii) You can also use the `summary` function to get a convenient table with the exact values of these parameters as well as the values of the inclusion Bayes factors and posterior probabilities for edge inclusion. There will be `inf` values for the inclusion Bayes factors for some of the edges; this simply means that the posterior inclusion probability is 1, so the Bayes factor calculation is undefined since the denominator is zero.

Task 2.2: Estimate the parameters without edge selection.

For this you need to specify the argument `edge_selection = FALSE` in the `easybgm` function. You can again use the `summary` function to see the estimated parameters. Notice that this table only contains the values of the estimated parameters, and not the inclusion Bayes factors and posterior inclusion probabilities.

Task 2.3: Determine Uncertainty of Interaction Parameters & Compare the results from Task 2.1 and Task 2.2.

- (i) Visualize the uncertainty of interaction parameters using the parameter forest plot. You can generate the plot with the `plot_parameterHDI` function. Do this for both the model with edge selection and the model without edge selection.
- (ii) How do you interpret credible intervals, especially the highest density interval? If you are unsure, there is more information on this in the tutorial paper or the JASP guidelines for reporting Bayesian analysis:

Van Doorn, J., Van Den Bergh, D., Böhm, U., Dablander, F., Derks, K., Draws, T., ... & Wagenmakers, E. J. (2021). The JASP guidelines for conducting and reporting a Bayesian analysis. *Psychon Bull Rev* 28, 813–826
- (iii) Compare the results from Task 2.1 and Task 2.2. What are the key differences between the two models in terms of the spread of the posterior distribution of the parameters.

Part 3: Reflection and Conceptual Understanding

(ii) Throughout the talk (and in detail in the tutorial paper <https://psyarxiv.com/ub5tc>), we mention the practical benefits of analyzing networks using a Bayesian approach. What are these benefits?

Optional Part 4: Prior robustness

Reviewer 2 criticizes you for using a Bayesian approach because they find the prior choices arbitrary. You want to be more certain that your results are not just based on your specific prior choices. You perform a prior robustness check. For more details on the priors used in the analysis of these models you can take a look at:

Sekulovski, N., Keetelaar, S., Haslbeck, J. M. B., & Marsman, M. (2024). Sensitivity Analysis of Prior Distributions in Bayesian Graphical Modeling: Guiding Informed Prior Choices for Conditional Independence Testing. *Advances in psychology*, e92355.

(i) What prior settings could you change to conduct a prior robustness check? Have a look at the `bgms` package to see what prior choices they allow.

(ii) Choose different settings for the prior argument(s) and re-estimate as well as visualize your results (using edge selection). How do the different choices of the prior affect your conclusions?

Optional Part 5: Test a Binary Network Model

Data background: A group of clinical researchers has contacted you to help them evaluate two recently collected data sets on symptoms of alcohol use disorder (AUD). One dataset is a large-scale survey collected from the general public. It consists of 15,000 individuals. The second dataset consists of individuals who have all been diagnosed with an alcohol use disorder in the past 12 months. Unfortunately, the clinical data consists of only 500 individuals because it is much more difficult to collect data on this subgroup.

The research group wants to assess the **structure** of AUD symptoms in both subgroups to determine the mechanisms that lead from recreational alcohol use to harmful alcohol dependence.

Both data sets include six symptoms of AUD, namely: (1) time spent drinking and obtaining alcohol, (2) tolerance (needing more alcohol for the same effect), (3) loss of control, (4) emotional problems related to alcohol use, (5) work problems due to alcohol use, and (6) engaging in risky activities while under the influence of alcohol.

Load the `data_clinical.csv` and `data_population.csv` data. Note that access to the real data is prohibited, so we use simulated data in this example. The datasets that you will use are simulated based on the characteristics of the original data.

```
data_clinical <- read_csv("data_clinical.csv")
data_population <- read_csv("data_population.csv")
```

Task 2.1: Estimate a Binary Network Model

Estimate a binary network model within `easybgm`. You have looked at previous network research on AUD and have reason to believe that 70% of the edges are present. How can you incorporate this information into the analysis? Take a look at the additional function arguments of `bgms` to see which additional argument you need to feed `easybgm`.

Task 2.2: Evaluate the Network Structure using the Edge Evidence Plot.

- (i) Compute the edge evidence plots using `plot_edgeevidence`.
- (ii) Interpret the network structure of both subgroups. Do the networks of the clinical and population sample differ and if so, what are the key distinctions?

Task 2.3: Network Comparison Test (developer version)

We are currently in the final stages of implementing a network comparison test in `bgms` that allows you to estimate and test if there is a difference in the edge weight parameters in the networks for two independent samples. If you want to give this a try, you can download the developer version of the package from GitHub (<https://github.com/MaartenMarsman/bgms>).

Task 2.4: Reflection and Conceptual Understanding

- (i) During the lecture, we specified the prior probabilities in a way that did not favor one structure over another. But we can also specify these probabilities to match certain expectations we may have about the structure of the network (e.g., the network is densely connected and has only positive relationships). What sources of information could we use to formulate our expectations about network structure before we see or analyze a new data set?
- (ii) For which of the two datasets or analyses do you think the Bayesian approach is most useful? And why?
